

Wholeness Statement The Priority Queue ADT stores any kind of object as a key object pair, but the keys must be objects that have a total order relation (or linear ordering). Each individual has access to the source of thought which is a field perfect order and balance.

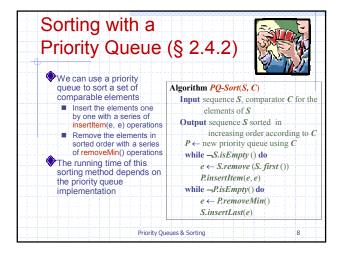

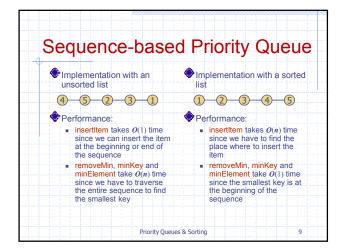

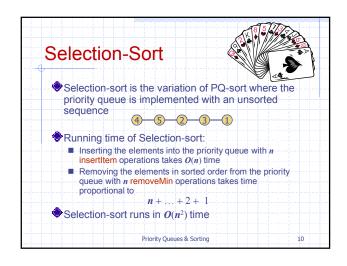

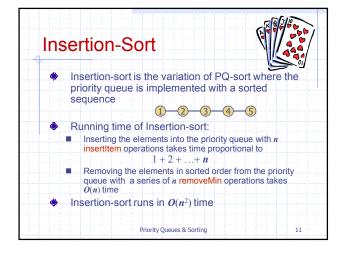

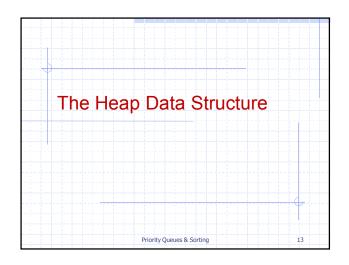

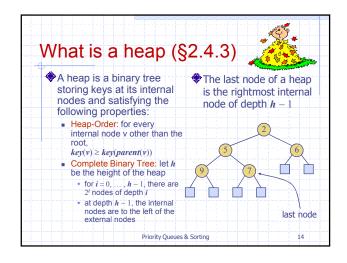

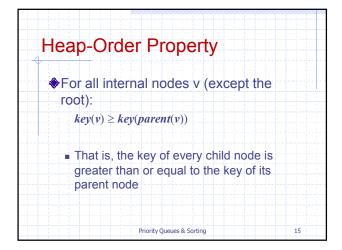

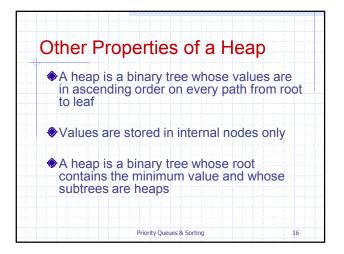

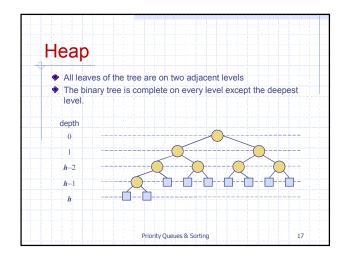

Main Point 1. Insertion sort starts with an initial list with one element, then inserts each new element such that the resulting sequence is also in order. Selection sort selects the smallest element each iteration from an unsorted list and inserts it at the end of the target list. Neither of these algorithms is optimal. Pure intelligence always follows the optimal law of least action.

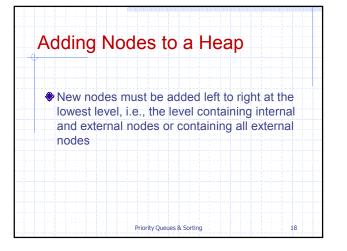

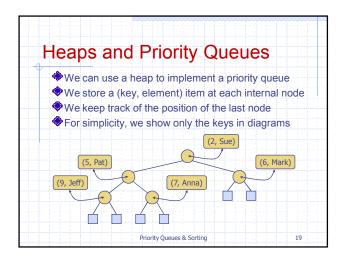

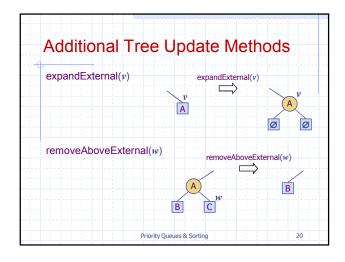

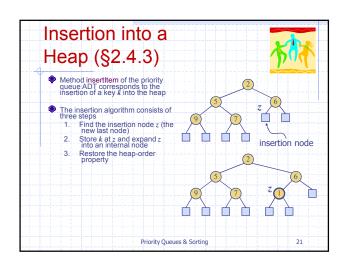

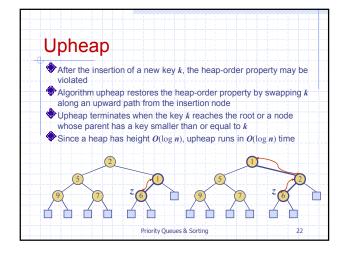

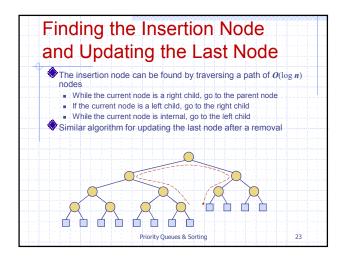

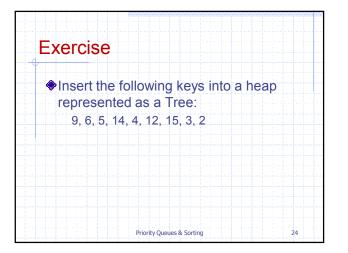

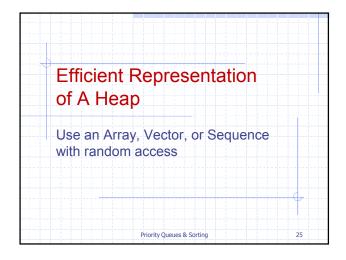

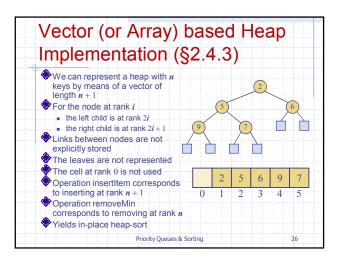

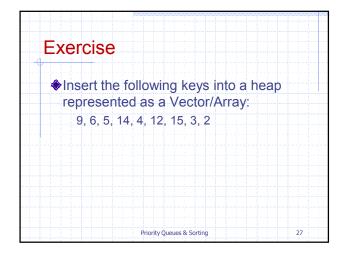

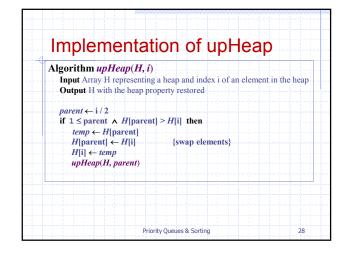

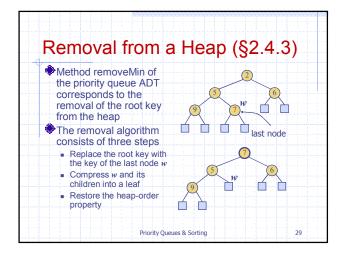

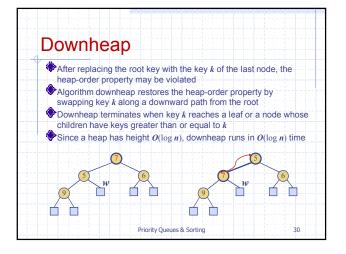

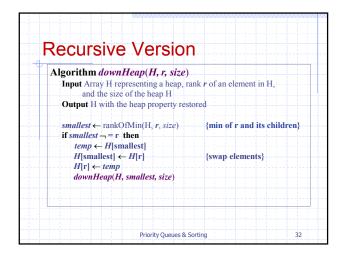

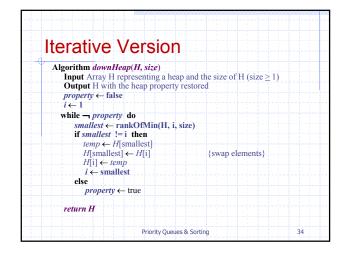

Exercise: Write the pseudocode for downHeap You can have any interface you wish You will need an extra argument, i.e., the size of the heap (Why?) The interface for a recursive version of upHeap was upHeap(H, i) So the interface of a recursive version would be downHeap(H, i, size) An iterative version would have interface downHeap(H, size)

Helper for downHeap Algorithm

Algorithm rankOfMin(A, r, size)
Input arrayA, a rank r (containing an element of A), and size of the heap stored in A
Output the rank of element in A containing the smallest value

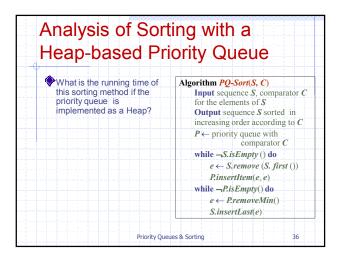

smallest ← r
left ← 2*r
right ← 2*r + 1
if left ≤ size ∧ A[left] < A[smallest] then
smallest ← left
if right ≤ size ∧ A[right] < A[smallest] then
smallest ← right
return smallest

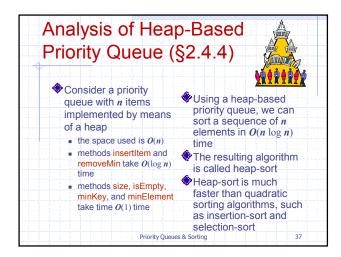

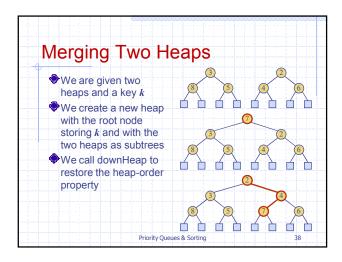

Analysis of Heap Operations

minKey()
minElement()
size()
isEmpty()

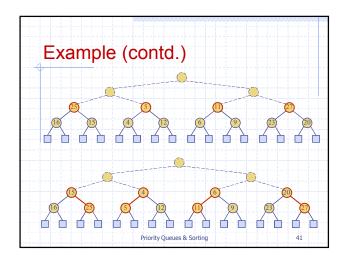

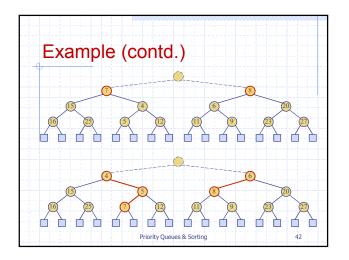

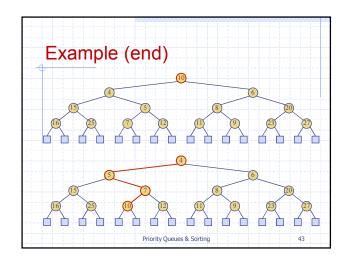

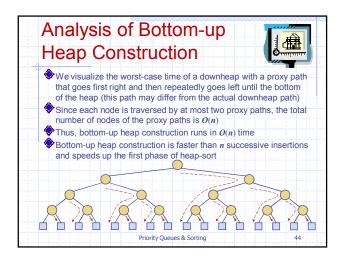

Main Point

A heap is a binary tree that stores key object pairs at each internal node and maintains heap-order and is complete.
 Heap-order means that for every node v (except the root), key(v)≥key(parent(v)).
 Pure consciousness is the field of wholeness, perfectly orderly, and complete.

Priority Queues & Sorting 45

Algorithm	Time	Notes
selection-sort	$O(n^2)$	\$ slow\$ in-place\$ for small data sets (< 1K)
insertion-sort	$O(n^2)$	slowin-placefor small data sets (< 1K)
heap-sort	$O(n \log n)$	♦ fast♦ in-place♦ for large data sets (1K — 1M)

Connecting the Parts of Knowledge with the Wholeness of Knowledge

- Sorting with a Priority Queue is a simple process of inserting the elements in the queue and removing them using the removeMin operation.
- How the Priority Queue is implemented determines its efficiency when used in a sort, i.e., if implemented as a Heap, then the sorting algorithm is optimal, O(n log n).

Priority Queues & Sorting

Transcendental Consciousness is the unbounded field of pure order and efficiency.

 Impulses within Transcendental Consciousness: The laws of nature are not the consciousness.

Consciousness: The laws of nature are nonchanging and universal which provide a reliable basis for the integrity of the universe.

 Wholeness moving within itself: In Unity Consciousness, life is spontaneously lived in accord with natural law for maximum achievement with minimum effort.
